

8051 Microcontroller Jumps and Calls *4/12/2019*

JT Wunderlich PhD

Recall Minimal Computer Architecture

- PROGRAM COUNTER (PC) addresses instructions to be fetched from memory
- INSTRUCTION REGISTER receives fetched instruction
- CONTROL LOGIC creates all routing signals after decoding the fetched instruction
- ARITHMETIC LOGIC UNIT (ALU) performs arithmetic and logical manipulation of data and addresses
- REGISTERS (i.e., general purpose registers) store intermediate results of calculations
- STATUS REGISTER holds status flags and condition codes, and two control bits for picking register bank to be in use
- “MEMORY” (i.e. “main memory”) stores data and instructions
- STACK stores addresses (or processor status) for returning from program-calls or interrupts
- INPUT/OUTPUT (“I/O”) often addressed as memory (i.e., memory-mapped I/O)

Recall Minimal Computer Architecture

■ Typical Instruction Format:

5 to 11 bits in OP-Code

Therefore $2^5=32$ to $2^{11}=2048$ different machine instructions in "**Instruction Set**"

- Some simple Microcontrollers (e.g., PIC's) have only 32 instructions
- Some large-scale machines (e.g., IBM S/390) have close to 2000 instructions

8051

■ Typical Instruction Format:

← 8 to 24 bits →

← →

8 bits in OP-Code

Therefore $2^8=256$ possible machine instructions in "**Instruction Set**"

8051 Memory Map

- Program Counter (“PC”) has 16 bits
 - Therefore $2^{16} = \underline{64K}$ of ADDRESS SPACE
of CODE MEMORY
 - 0000 to FFFF hex
 - Separated into 32 2K PAGES

Addressing Modes vs. Ranges

■ Modes

1. Immediate
2. Register
3. Direct
4. Indirect

■ Range

1. “Relative-Range”
2. “Short-Absolute”
3. “Long-Absolute”

Absolute just
meaning not relative

Addressing Modes vs. Ranges

■ Modes

1. Immediate *means operand data is encoded by you into instruction*
2. Register *means operand data is in registers*
3. Direct *means operand data is at location encoded by you into instruction*
4. Indirect *means operand data is at location specified in a register*

Address RANGES

and Branch-target Address Formation

- “Relative-Range”
 - $(PC) \leftarrow (PC) + \text{Instruction length} + \text{“Radd”}$
 - Radd = 1-byte relative address encoded into instruction (-128 to 127) in 2’s compliment
- “Short-Absolute” (**Absolute within $2^{11} = 2K$ page**)
 - $(PC) \leftarrow (PC) + \text{Instruction length}$
 - $(PC \text{ bits } 11 \text{ to } 0) \leftarrow \text{“Sadd”}$
 - Sadd = Assembler uses 1-byte encoded into instruction to create an 11-bit Sadd (e.g, mapped to a label – assembler error if label on another page)
 - (PC bits 15 to 12) are fixed and indicate which page you are on
- “Long-Absolute”
 - $(PC) \leftarrow (PC) + \text{Instruction length}$
 - $(PC \text{ bits } 15 \text{ to } 0) \leftarrow \text{“Ladd”}$
 - Ladd = 2-bytes encoded into instruction

Short (relative RANGE)

INSTRUC

When to Jump

Other Actions

JC	(C) = 1	
JNC	(C) not= 1	
JB	(bit address) = 1	
JNB	(bit address) not= 1	
JBC	(bit address) = 1	Make (bit address) = 0
CJNE	operand 1 not= operand 2	(C) = 1 if Op1 < Op2
DJNZ	operand 1 not= 0	Decrement first
JZ	(A) = 0	
JNZ	(A) not= 0	
<u>S</u> JMP	Always (i.e., “unconditionally”)	

Page (Absolute RANGE within page)

INSTRUC When to Jump

Other Actions

<u>A</u> JMP	always	
<u>A</u> CALL	always	PUSH address of next instruction onto stack so you can return from this subroutine "Call" $((SP)) \leftarrow (PC) + \text{instruction length}$
RET	always	POP address of next instruction off of stack so you can return from subroutine with this instruction last in it $(PC) \leftarrow ((SP))$

Long (to anywhere in space)

INSTRUC When to Jump

Other Actions

INSTRUC	When to Jump	Other Actions
<u>L</u> JMP	always	
<u>L</u> CALL	always	PUSH address of next instruction onto stack so you can return from this subroutine "Call" $((SP)) \leftarrow (PC) + \text{instruction length}$
RET	always	POP address of next instruction off of stack so you can return from subroutine with this instruction last in it $(PC) \leftarrow ((SP))$

Special Case

to access **external memory space**

INSTRUC When to Jump

Other Actions

JMP	always	$(PC) \leftarrow (A) + (DPTR)$ DPTR is a 16 bit pointer Ground "EA" pin on chip to force all code fetches to be from external memory (via port pins)
RET	always	POP address of next instruction off of stack so you can return from subroutine with this instruction in it $(PC) \leftarrow ((SP))$

Compare RANGE's

- “Relative-Range”
 1. Only one byte for branch target formation
 2. Limited jump range (-128 to 127)
 3. If relocating code, watch page-boundaries
- “Short-Absolute” (Absolute *within* $2^{11} = 2K$ page)
 1. Only one byte needed to begin branch target formation
 2. Better jump range (2K of options)
 3. If relocating code, watch page-boundaries
- “Long-Absolute”
 1. Two bytes needed for branch target formation
 2. Best jump range (64K of options, i.e., entire space)

Focusing on the Blurry Distinction between Microprocessors and Microcontrollers

J. T. Wunderlich PhD

Elizabethtown College (**present**) and Purdue University (**1999**)

Abstract

This paper compares microprocessors and microcontrollers in the context of teaching a sophomore level course where students have completed previous studies in digital circuits and programming. Discussing the similarities between these devices helps reinforce the understanding of the basic function of either device. Topics such as the "fetch-decode-execute" of an instruction cycle, or the memory-mapping of I/O provide good examples of similarities. Discussing the differences helps identify which device is most suitable for a given application. Topics such as mathematical computation capabilities or the ability to contain all needed functionality on a single chip provide good examples of differences. It is also important to study these devices in the context of historical trends since today's microcontrollers have evolved from past microprocessors. The microcontroller of the future could look more like today's microprocessors -- with a wider data bus, enhanced mathematical functionality, and numerous speed-up schemes. However, many of the unique features of microcontrollers are unlikely to be found in future microprocessors -- the separate memory for instructions and data is one example; the on-chip I/O control features such as analog-to-digital conversion and pulse-width-modulated outputs are other examples. The understanding of microprocessors and microcontrollers can also be enhanced by considering the differences between how programmers and engineers may view these devices. For example, a device could be selected for the programming power of the instruction-set, or for the simplicity of the instruction-set and minimization of additional circuitry.
